ABSTRACT

Spatio-temporal data is utilized in various fields, but its scale is generally vast, leading to significant labor and costs in storage and processing. Therefore, the value that can be derived from spatiotemporal data is diluted due to management costs. We propose a new data management flow using various metadata and common programs for spatio-temporal data utilization. Traditionally, various spatio-temporal data processing have been implemented and processed according to each spatio-temporal data. We defined spatiotemporal data structure metadata and performed data processing based on metadata using a common data processing program. Furthermore, we automated the generation of data structure metadata by combining our data skeleton recognition method and generative AI model. Using this flow, we expect to improve the sustainability of utilizing spatio-temporal data.

1 INTRODUCTION

Spatio-temporal data is utilized in various fields such as transportation, weather, disaster management, and marketing, providing some "value" within these fields. Various studies have also been conducted on the management of spatio-temporal data [4]. However, many spatio-temporal datasets are so large that the effort and cost involved in management can dilute the value that can be derived from the data. According to a survey by Anaconda [1], 37.75% of data analysts' efforts are devoted just to data preparation and cleansing. As a result, there are cases where spatio-temporal data analysis is abandoned, and the data is left unutilized or discarded.

We propose a new data management flow for automating spatiotemporal data processing for data analysis, and a metadata format along with a method for generating metadata for spatio-temporal data structure, as depicted in Figure 1. We define metadata representing the structure of spatio-temporal data, data collection methods, and storage locations. In addition, we define a template for the data processing program, enabling the implementation of various data processing tasks. We also introduce a method for automatically generating the structural metadata for automating data processing, by combining our data skeleton recognition method and generative

2 DATA MANAGEMENT FLOW DESIGN

management flow using them.

Overview: This flow (Figure 1) consists of multiple modules used in the stages of collection, organization, conversion, and utilization of spatio-temporal data. In addition, the JSON-LD database manages the metadata generated at each stage. The following describes the details of each module.

JSON-LD Metadata Database: In the domain of the semantic web and Linked Open Data, studies have been undertaken to attach semantic metadata to spatio-temporal data using ontologies and to describe data relationships with RDF and/or JSON-LD [2, 3, 5]. We have expanded these ideas and developed a format that represents various metadata for spatio-temporal data (e.g., sources of spatiotemporal data, storage locations, data structures, and conversion programs used) in JSON-LD. In addition, we have developed a database and user interface to manage these metadata easily.

Collection: A lot of spatio-temporal data is collected from a large number of devices such as smartphones and IoT sensors. Therefore, data loss can occur when individual devices encounter problems during data collection, posing challenges for spatio-temporal data analysis. In this flow, communication from each device is proxied, and the data collection status is automatically recorded in a JSON-LD database.

Organization: In this flow, we organize spatio-temporal data through 1) metadata tagging and 2) tiering of data. As shown in Figure 2, spatio-temporal data is first input to the skeleton recognition engine, which outputs the skeleton information. The spatiotemporal data is then input together with the skeleton information to a generative AI model (ChatGPT), which assigns metainformation about the data itself (e.g., what values it represents, units, etc.). In addition, we define storage metadata for various storage destinations and perfome data tiering according to usage situations.

Conversion and Utilization: In this flow, parameters required for data conversion are generalized, and data conversion is performed using data conversion programs with metadata related to functionality, as shown in Figure 3. This improves the traceability of spatio-temporal data and enables the reproduction and scaling of conversion processes.

3 EXPERIMENT: METADATA TAGGING

We conducted experiments on metadata tagging for several spatiotemporal datasets using the structural metadata tagging system we developed. The results showed that, in many cases, the system could recognize the overall structure of the data and appropriate labels and qualitative characteristics for each variable in well-structured JSON/CSV data, as shown in Figure 4. However, it was also observed that the system could not fully capture the data structure and variable characteristics in spatio-temporal data where the number of CSV columns varied by row or when the variables themselves had few distinctive features. We are now working to address these issue by updating the skeleton recognition engine algorithm and the prompt for ChatGPT.
